

Crosstalk Lab

Multi-model triangulation for epistemic sense-making

The dominant paradigm for AI interaction is one model, one conversation, one perspective. Ask a question, get an answer. This is useful. It is also systematically incomplete.

Crosstalk Lab is built on a different premise: that the most generative use of AI is not any single model's output, but the *structure of disagreement and convergence* across multiple models engaging the same question.

What It Does

Crosstalk runs your prompts through Claude, ChatGPT, and Gemini simultaneously and surfaces their responses side by side. But the core feature isn't parallel display — it's what happens after.

A structured dialogue layer lets you route any model's response to any other model as input. Claude can react to Gemini's framing. ChatGPT can pressure-test Claude's argument. You moderate the conversation; the models do epistemic work on each other's outputs.

The result is a triangulation session: not three answers to your question, but a multi-voice investigation of the question's terrain.

Why Triangulation

The metaphor is geometric. Surveyors don't measure a point directly — they take bearings from multiple fixed positions and let the geometry locate it. Applied epistemically: when three models with different training histories, architectures, and tendencies converge on a claim, that convergence is meaningful. When they diverge, the divergence is the finding.

This is grounded in Bakhtin's concept of *outsideness* — the idea that any perspective has a surplus of seeing unavailable from within. No single model has access to its own blind spots. A second model, positioned differently, can see what the first cannot. A third closes the triangle.

What It's For

Crosstalk is not a productivity tool. It does not help you get tasks done faster.

It is a sense-making tool — for researchers developing a position, educators designing curriculum, analysts stress-testing a conclusion, writers examining an argument from multiple angles. Anyone for whom the quality of thinking matters more than the speed of output.

The session itself is the artifact. Structured exports preserve the full dialogue — routing decisions, model attributions, turn sequence — because the architecture of a triangulation session carries meaning independent of its content.

Current Status

Crosstalk Lab is in active development, deployed at yourcrosstalklab.com and accessible by invitation. It runs entirely in the browser with no server-side key handling — your API credentials never leave your machine.

Implemented features include parallel mode, structured dialogue routing (Conductor mode), per-model role assignment, session export, and encrypted portable API key files.
